- Put the origin of all three arrows at the mean of your data points
- Draw PC1 and PC2 as arrows in their respective directions. Their lengths are arbitrary if you're just illustrating direction; you could draw unit-length arrows.
- Imagine a flat plane passing through the mean and spanned by PC1 and PC2.
- Project every data point onto that plane. Each point moves perpendicular to the plane onto its closest location on it.
- Ignore PC3. The small amount of variation along that direction is what you lose when reducing to two dimensions.
